ON THE SACKS-UHLENBECK FLOW OF RIEMANNIAN SURFACES

MIN-CHUN HONG AND HAO YIN

Abstract. In this paper, we study an α-flow for the Sacks-Uhlenbeck functional on Riemannian surfaces and prove that the limiting map by the α-flows is a weak solution to the harmonic map flow. By an application of the α-flow, we present a simple proof of an energy identity of a minimizing sequence in each homotopy class.

1. Introduction

Suppose that M is a Riemannian manifold and N is a closed manifold embedded in $\mathbb{R}^k$. A critical point u of the Dirichlet energy

$$E(u) = \int_M |\nabla u|^2 \, dv$$

is called a harmonic map.

Harmonic maps between Riemannian manifolds can be thought of as a natural generalization of geodesics, minimal surfaces and harmonic functions. A fundamental question is: Given a smooth map u_0 from M to N, does there exist a smooth harmonic map representative in the homotopy class of u_0? In a pioneering work [7], Eells and Sampson introduced the harmonic map flow and used it to deform an initial map to a harmonic map in the same homotopic class if the sectional curvature of N is non-positive. In general, one cannot expect to have the existence of smooth harmonic maps into general target manifolds due to the fact that singularities do occur. From now on, we assume that M is a closed Riemannian surface, hence $E(u)$ is conformally invariant. Under certain topological conditions of N, the existence of minimizing harmonic maps in a homotopy class was proved by Lemaire [11] and Schoen-Yau [21]. In a well-known paper [18], Sacks and Uhlenbeck proposed a family of the perturbed functional

$$E_\alpha(u) = \int_M (1 + |\nabla u|^2)^\alpha dv$$

for $\alpha > 1$. The advantage of the perturbed functional is that E_α satisfies the Palais-Smale condition and therefore it is easy to obtain critical points of E_α by either minimizing energy functional or Morse theory. When $\alpha \to 1$, the limiting map of critical points of E_α is a harmonic map and a bubbling phenomenon occurs.

On the other hand, Struwe [22] proved the global existence of the weak solution to the harmonic map flow and that the solution to the flow converges to a harmonic map as $t \to \infty$. Chang, Ding and Ye [2] constructed an example that the harmonic

Key words and phrases. harmonic map flow, Sacks-Uhlenbeck functional.

map flow blowups at finite time, so in general the limit harmonic map by the flow may not be in the same homotopy class of the initial map.

In this paper, we study an α-flow for the perturbed energy E_α in the same homotopy class of the initial map. More precisely, we consider the following evolution problem:

$$\partial_t u = \triangle_M u + (\alpha - 1)\frac{\nabla |\nabla u|^2 \cdot \nabla u}{1 + |\nabla u|^2} + A(u)(\nabla u, \nabla u) \tag{1.1}$$

with $u(x, 0) = u_0$, where $\triangle_M$ is the Laplacian operator with respect to the Riemannian metric of M and A is the second fundamental form of N. We call (1.1) the Sacks-Uhlenbeck flow (or α-flow). We would like to point out that the α-flow is not the standard gradient flow, but the flow has some analytic advantage.

At first, we have

Theorem 1.1. *For a given smooth map $u_0 : M \to N$, there exists a unique global smooth solution $u_\alpha(x, t)$ to the evolution problem (1.1) in $M \times [0, \infty)$. Moreover, for any $t_i \to \infty$, $u_\alpha(\cdot, t_i)$ converges smoothly to a limit map u_α, which is a critical point of the Sacks-Uhlenbeck functional for $\alpha - 1$ sufficiently small.*

For each $\alpha > 1$, let $u_\alpha(x, t)$ be the global smooth solution to (1.1) in the same homotopy class with the initial map u_0 from M to N. There is a nature problem to study the limit behaviour of the solution $u_\alpha(x, t)$ as $\alpha \to 1$ as one in [18]. Thus, we prove

Theorem 1.2. *(i) As $\alpha \to 1$, the solution u_α converges smoothly to u on $M \times [0, \infty) \setminus \Sigma$, where the concentration set Σ is a closed set defined by*

$$\Sigma = \bigcap_{0<R<R_M} \left\{ z \in M \times [0, \infty) | \quad \liminf_{\alpha \to 1} \Psi_R^\alpha(u_\alpha, z) \ge \varepsilon_0 \right\}$$

for some ε_0 to be determined. For the precise definition of Ψ_R^α, see Section 3.

(ii) For any two positive t_1 and t_2, $\mathcal{P}^2(\Sigma \cap (M \times [t_1, t_2]))$ is finite, where $\mathcal{P}^2$ denotes the 2-dimensional parabolic Hausdorff measure. Moreover, for any $t \in (0, +\infty)$, $\Sigma_t = \Sigma \cap (M \times \{t\})$ consists of at most finitely many points.

(iii) u is a weak solution to the harmonic map flow.

In fact, this result is similar to the one by the Ginzburg-Landau flow approximation. In [4], Chen and Struwe used the Ginzburg-Landau flow approximation to construct a global weak solution of the harmonic map flow for any dimension larger than two. Further results obtained by the Ginzburg-Landau flow were discussed by Lin and Wang in [15]. The method by the Ginzburg-Landau flow is very powerful to show the global existence and partial regularity of a weak solution to the harmonic map flow, but it seems that the flow loses control on the topological quantity of maps. The advantage of the Sacks-Uhlenbeck flow approximation is that the solution u_α remains in the same homotopy class of u_0, therefore it seems that the Sacks-Uhlenbeck flow provides a nice geometric picture and can be used to have some geometric applications (see Theorem 1.4 below).

Without the assumption of the energy inequality, weak solutions to the heat flow for harmonic maps may not always be unique (see [1] and [24]), so it is very interesting whether the limiting solution u by the Sacks-Uhlenbeck flow is the global weak solution $\hat{u}$ constructed by Struwe in [22]. Although we do not have a complete answer to the question, we can compare some property of u with the one of $\hat{u}$ in the following:

Theorem 1.3. *(i) The first concentration time for* u_α *as* $\alpha \to 1$*; i.e.*

$$T = \inf_{(x,t)\in\Sigma} t$$

is the same as the first singular time of the Struwe's weak solution. Hence, u_α *converges smoothly to the Struwe's solution in* $M \times [0, T)$*.*

(ii) Consider the following two limits of measures

$$|\nabla \hat{u}(\cdot, t)|^2 dv \to |\nabla \hat{u}(\cdot, T)|^2 dv + \sum_{i=1}^{\hat{k}} \hat{m}_i \delta_{\hat{p}_i} \quad \text{as } t \to T$$

and

$$(1 + |\nabla u_\alpha(T, \alpha)|^2)^\alpha dv \to (1 + |\nabla u(\cdot, T)|^2)\, dv + \sum_{i=1}^{k} m_i \delta_{p_i} \quad \text{as } \alpha \to 1.$$

Then $k = \hat{k}$*,* $p_i = \hat{p}_i$ *and* $\hat{m}_i \geq m_i$*.*

Moreover, we can obtain more refined information about the singularity points of u and Σ (see Lemma 3.3).

In the final part of this paper, we apply the $\alpha-$flow to study a minimizing sequence in a given homotopy class. Let u_i be a sequence of smooth maps minimizing $E(u) = \int_M |\nabla u|^2\, dv$ in a fixed homotopy class of maps. Since u_i is bounded in $W^{1,2}$, there is a weak limit u in $W^{1,2}(M, N)$. In general, u may not be in the same homotopy class, but we can show:

Theorem 1.4. *Let* u *be the weak limit of above minimizing sequence* $\{u_i\}$*. Then it is a harmonic map from* M *to* N *and there exist harmonic maps* $\omega_k : S^2 \to N$ *with* $k = 1, \cdots, l$ *such that*

$$\lim_{i\to\infty} E(u_i) = E(u) + \sum_{k=1}^{l} E(\omega_k). \tag{1.2}$$

Moreover, if $\pi_2(N)$ *is trivial, then* u_i *converges strongly to* u *in* $W^{1,2}(M, N)$ *and* u *is a minimizer in the homotopy class of* u_i*.*

The last part of this theorem can be compared with Theorem 5.1 of [18], where under the same assumption that $\pi_2(N)$ is trivial, the existence of a minimizer in each homotopy class is proved (see also [21] and [11]). We improve the result a little by obtaining that every smooth minimizing sequence converges to such a minimizer. In the proof, we use the $\alpha-$flow to modify the original minimizing sequence and study the blow-up of the new sequence as Theorem 5.1 in [18]. The energy identity of minimizers of the Sacks-Uhlenbeck functional was implicitly established by Chen and Tian in [3]. Our proof for the energy identity is different from one in [3]. Although the result of Theorem 1.4 may be regarded as a consequence of the theory developed by Duzaar and Kuwert [6], the advantage is that we can avoid to use the concept "weak homotopy class" of maps in the Sobolev space $W^{1,2}(M, N)$, which is formulated by big machinery. Finally, we would like to mention that the related energy identity of critical points of the Sacks-Uhlenbeck functionals was recently discussed by Li and Wang [13] and by Lamm [10].

Remark 1.5. *After we finished a first version of this paper, Yuxiang Li informed us that in* [14] *they used a similar idea to show the energy identify for a sequence of minimizers of E_α when $\alpha \to 1$. In fact, while Li and Wang in* [14] *used a reduction procedure of Ding and Tian* [5]*, we use the bubble tree construction of Parker in* [17] *and Lemma 5.4 to find the connecting geodesics, so our approach is different.*

The paper is organized as follows. In Section 2, we prove Theorem 1.1. In Section 3, we give a proof of Theorem 1.2. In Section 4, we complete a proof of Theorem 1.3 except for the energy identity, which is proved in Section 5.

2. GLOBAL EXISTENCE AND CONVERGENCE OF $\alpha-$FLOW

This section is devoted to the proof of Theorem 1.1. In local coordinates $g = (g_{ij})$, the α-flow can be written as

$$\partial_t u = \frac{1}{\sqrt{|g|}}\frac{\partial}{\partial x_i}\left(\sqrt{|g|}g^{ij}\frac{\partial u}{\partial x_j}\right) + (\alpha-1)\frac{g^{ij}\frac{\partial}{\partial x_i}|\nabla u|^2\frac{\partial u}{\partial x_j}}{1+|\nabla u|^2} + A(u)(\nabla u, \nabla u).$$

This system is a nonlinear parabolic system. For a smooth initial value u_0, the local existence of the system can be shown (see below appendix for details in Section 6); i.e., there exists $T > 0$ and a smooth solution $u(x,t)$ defined on $[0,T)$. The proof of Theorem 1.1 follows if one can establish C^k uniform estimates of $u(x,t)$ independent of T for any $t \in [0,T)$.

The first observation is that

Lemma 2.1. *If $u(x,t)$ is a solution to the $\alpha-$flow, then $E_\alpha(u(\cdot,t))$ decreases in t.*

Proof. Multiply (1.1) by $(1+|\nabla u|^2)^{\alpha-1}\partial_t u$ and integrate by parts. ☐

The next lemma is a local version of the energy inequality.

Lemma 2.2. *Let u be a solution to the $\alpha-$flow. Then*

$$\int_{B_R(x)}(1+|\nabla u(\cdot,t_2)|^2)^\alpha dv \le \int_{B_{2R}(x)}(1+|\nabla u(\cdot,t_1)|^2)^\alpha dv + C\frac{t_2-t_1}{R^2}E_0 \tag{2.1}$$

for $t_1 < t_2$. Here E_0 is some upper-bound of the overall energy.

Proof. Let φ be a cut-off function supported in $B_R(x)$ and $\varphi \equiv 1$ on $B_{R/2}(x)$. Multiplying the equation (1.1) by $(1+|\nabla u|^2)^{\alpha-1}\partial_t u\varphi^2$, we obtain

$$\begin{aligned} & \int_M (1+|\nabla u|^2)^{\alpha-1}|\partial_t u|^2\varphi^2 dv \\ = \;& -\int_M (1+|\nabla u|^2)^{\alpha-1}\nabla u\nabla\frac{\partial u}{\partial t}\varphi^2 dv - \int_M (1+|\nabla u|^2)^{\alpha-1}\nabla u\frac{\partial u}{\partial t}2\varphi\nabla\varphi dv \\ \le \;& -\frac{1}{\alpha}\frac{d}{dt}\int_M (1+|\nabla u|^2)^\alpha\varphi^2 dv + \frac{1}{2}\int_M (1+|\nabla u|^2)^{\alpha-1}|\partial_t u|^2\varphi^2 dv \\ & + \int_{B_{2R(x)}}(1+|\nabla u|^2)^{\alpha-1}|\nabla u|^2\frac{C}{R^2}dv. \end{aligned}$$

Hence,

$$\int_{B_R(x)}(1+|\nabla u(\cdot,t_2)|^2)^\alpha dv \le \int_{B_{2R}(x)}(1+|\nabla u(\cdot,t_1)|^2)^\alpha dv + C\frac{t_2-t_1}{R^2}E_0.$$

☐

The second key for the proof of Theorem 1.1 is to derive a Bochner type formula. We consider a scaled version of (1.1) for some $r > 0$,

$$(r^2+|\nabla u|^2)^{\alpha-1}\partial_t u = \operatorname{div}\left((r^2+|\nabla u|^2)^{\alpha-1}\nabla u\right) + (r^2+|\nabla u|^2)^{\alpha-1}A(u)(\nabla u,\nabla u). \tag{2.2}$$

Locally, we choose an orthonormal frame $\{e_1, e_2\}$. We use ∇_i for the first covariant derivative with respect to e_i. We denote by u_{ji} the second covariant derivatives of u and so on. Of course, we assume summation convention for repeated index. Then

Lemma 2.3. *Let $u(x,t)$ be a smooth solution to the scaled $\alpha-$flow (2.2). If $\alpha - 1$ is small, then the following Bochner type formula is true:*

$$\frac{\partial}{\partial t}e(u) - \nabla_i\left((\delta_{ij} + 2(\alpha-1)\frac{u_i^\beta u_j^\beta}{r^2+|\nabla u|^2})\nabla_j e(u)\right) \le Ce(u)(e(u)+1), \tag{2.3}$$

where $e(u) := |\nabla u|^2$.

Proof. The proof is by computation. In the following proofs, we assume $\alpha - 1$ is small whenever necessary. In a local frame, we have

$$\nabla_j e(u) = 2u_k^\gamma u_{kj}^\gamma, \quad |\nabla^2 u|^2 = \sum_{k,i,\gamma}|u_{ki}^\gamma|^2$$

Then we have

$$\begin{aligned}
&\nabla_i\left((\delta_{ij} + 2(\alpha-1)\frac{u_i^\beta u_j^\beta}{r^2+|\nabla u|^2})\nabla_j e(u)\right)\\
= \;& 2\nabla_i\left(u_k^\gamma u_{ki}^\gamma + 2(\alpha-1)\frac{u_i^\beta u_j^\beta u_k^\gamma u_{kj}^\gamma}{r^2+|\nabla u|^2}\right)\\
\ge \;& 2|\nabla^2 u|^2 + 2u_k^\gamma u_{iik}^\gamma + 4(\alpha-1)\nabla_i\left(\frac{u_i^\gamma u_k^\gamma u_j^\beta u_{kj}^\beta}{r^2+|\nabla u|^2}\right) - Ce(u)\\
\ge \;& \frac{3}{2}|\nabla^2 u|^2 + 2u_k^\gamma u_{iik}^\gamma + 4(\alpha-1)\frac{u_i^\gamma u_k^\gamma u_j^\beta u_{kji}^\beta}{r^2+|\nabla u|^2} - Ce(u)\\
\ge \;& |\nabla^2 u|^2 + 2u_k^\gamma\nabla_k\left(u_{ii}^\gamma + 2(\alpha-1)\frac{u_i^\gamma u_j^\beta u_{ji}^\beta}{r^2+|\nabla u|^2}\right) - Ce(u).
\end{aligned}$$

Here we have used twice Ricci identity for switching third order derivatives. Using (2.2), we have

$$\begin{aligned}
&\frac{\partial}{\partial t}e(u) - \nabla_i\left((\delta_{ij} + 2(\alpha-1)\frac{u_i^\beta u_j^\beta}{r^2+|\nabla u|^2})\nabla_j e(u)\right)\\
\le \;& -|\nabla^2 u|^2 - 2u_k^\gamma\nabla_k\left(A^\gamma(u)(\nabla u,\nabla u)\right) + Ce(u)\\
\le \;& Ce(u)(e(u)+1).
\end{aligned}$$

□

Using this Bochner formula, we can prove a small energy estimate following a method of Schoen [20] and Struwe [23]. In our case, the small energy assumption is automatically true because of the Hölder inequality and the E_α energy bound. More precisely, we have

Lemma 2.4. *There is a constant C independent of (x,t) for $x \in M$ and $t \in [0,T)$ such that*

$$|\nabla u|(x,t) \le C.$$

Proof. For any $t \in [0,T)$, Lemma 2.1 implies that

$$\int_M (1+|\nabla u|^2)^\alpha(t)dv \le C.$$

By the Hölder inequality, there exists a uniform constant $r_0 > 0$ such that for all $x \in M$ and $t < T$,

$$\int_{B_{r_0}(x)} |\nabla u(\cdot,t)|^2 \, dv \le \varepsilon_0.$$

Here ε_0 is a small constant to be determined. Since u is smooth in $M \times [0,T)$, it suffices to prove the lemma near $t = T$. By choosing r_0 sufficiently small, we may assume $r_0^2 < T$. Take any $x_0 \in M$ and $t_0 \in (r_0^2, T)$. Set

$$P_r = \{(x,t) | x \in B_r(x_0) \quad \text{and } t_0 - r_0^2 \le t \le t_0\}.$$

We can find $\rho \in [0, r_0]$ such that

$$(r_0-\rho)^2 \sup_{P_\rho} e(u) = \max_{\sigma \in [0,r_0]} \left\{ (r_0-\sigma)^2 \sup_{P_\sigma} e(u) \right\}.$$

Let (x_1,t_1) be the point in P_ρ such that

$$e \overset{\triangle}{=} e(u)(x_1,t_1) = \sup_{P_\rho} e(u).$$

If $e(r_0-\rho)^2 \le 4$, then

$$(\frac{r_0}{2})^2 \sup_{P_{r_0/2}} e(u) \le e(r_0-\rho)^2 \le 4,$$

which means the lemma is proved. Hence, we may assume that $e(r_0-\rho)^2 > 4$. Set

$$v(x,t) = u(x_1 + \frac{x}{e^{1/2}}, t_1 + \frac{t}{e})$$

for $(x,t) \in B_1(0) \times [-1,0]$. By our definition of v and the scaling invariance of Dirichlet energy, we have

$$\sup_{t\in[-1,0]} \int_{B_1(0)} e(v)dv \le \varepsilon_0. \tag{2.4}$$

Moreover, we have $e(v)(0,0) = 1$ and

$$\sup_{B_1(0)\times[-1,0]} e(v) \le e^{-1} \sup_{P_{\frac{r_0+\rho}{2}}} e(u) \le e^{-1} \frac{e(r_0-\rho)^2}{(r_0 - \frac{r_0+\rho}{2})^2} \le 4. \tag{2.5}$$

By Lemma 2.3 and (2.5),

$$\frac{\partial}{\partial t} e(v) - \nabla_i(a_{ij}(v)\nabla_j e(v)) \le Ce(v),$$

where

$$a_{ij}(v) = \delta_{ij} + 2(\alpha-1)\frac{v_i^\beta v_j^\beta}{r^2 + |\nabla v|^2}.$$

The symmetric matrix $(a_{ij}(v))$ has eigenvalues satisfy the uniform elliptic condition. In local coordinates, we can write the above inequality as

$$\partial_t e(v) - \frac{1}{\sqrt{|g|}} \frac{\partial}{\partial x_i} \left(\sqrt{|g|} (g^{ij} + \frac{(\alpha-1)}{r^2 + |\nabla v|^2} g^{ik} \frac{\partial v^\beta}{\partial x_k} g^{jl} \frac{\partial v^\beta}{\partial x_l}) \frac{\partial e(v)}{\partial x_j} \right) \leq Ce(v).$$

By a standard Moser iteration and (2.4), we have

$$1 = e(v)(0,0) \leq C \left(\int_{B_1(0)\times[-1,0]} e(v)^2 \right)^{1/2}.$$

By (2.5), we obtain

$$1 \leq C \int_{B_1(0)\times[-1,0]} e(v) \leq C\varepsilon_0,$$

which is a contradiction if we choose ε_0 small. □

We now complete the proof of Theorem 1.1.

Proof. Lemma 2.4 provides the C^0−uniform estimate for $u(x,t)$. Then we show higher order estimates. For $x_0 \in M$ and $T/2 < t_0 < T$, set $P_r = B_r(x_0) \times [t_0 - r^2, t_0]$. Suppose φ is a cut-off function supported in $P_{T/2}$ and $\varphi \equiv 1$ in $P_{T/4}$. Multiplying (1.1) by φ, we obtain

$$\partial_t(u\varphi) - \triangle(u\varphi) = (\alpha-1)\frac{(\nabla^2(u\varphi), \nabla u)\nabla u}{1+|\nabla u|^2} + \mathcal{R}[\varphi, u, \nabla u], \tag{2.6}$$

where $\mathcal{R}$ is a term involving $u, \nabla u$ and derivatives of φ. By Lemma 2.4 and the L^p estimate of linear parabolic equations, we have

$$\|\varphi u\|_{W^{2,p}(P_{T/2})} \leq C(\alpha-1)\left\|\nabla^2(\varphi u)\right\|_{L^p(P_{T/2})} + C,$$

for any $p > 0$. When $\alpha - 1$ is small,

$$\|\varphi u\|_{W^{2,p}(P_{T/2})} \leq C.$$

We then take one more space derivative of (2.6) to get

$$\partial_t(\varphi\nabla u) - \triangle(\varphi\nabla u) = (\alpha-1)\frac{(\nabla^3(\varphi u), \nabla u)\nabla u}{1+|\nabla u|^2} + \mathcal{Q}[\varphi, u, \nabla u, \nabla^2 u].$$

Here $\mathcal{Q}$ involves $u, \nabla u, \nabla^2 u$ and derivatives of φ. Using L^p estimate again, we have (when $\alpha - 1$ is sufficeintly small)

$$\|\varphi u\|_{W^{3,p}(P_{T/2})} \leq C,$$

for any p. Therefore,

$$\|\partial_t \nabla(\varphi u)\|_{L^p(P_{T/2})}, \quad \left\|\nabla^2(\varphi u)\right\|_{L^p(P_{T/2})} \leq C.$$

For $p > 3$, the Sobolev embedding theorem yields that

$$\|\nabla(\varphi u)\|_{C^\beta(P_{T/2})} \leq C$$

for some $\beta > 0$. We can now apply the Schauder theory for parabolic equations to obatin higher order estimates, which means that we can extend the solution $u(x,t)$ smoothly to $t = T$. Then the local existence result for smooth initial data implies $T = \infty$. □

3. THE LIMITING BEHAVIOUR OF THE SACKS-UHLENBECK FLOW

For a fixed initial map u_0, it follows from Theorem 1.1 that there is a unique global solution u_α to (1.1)in $M \times [0, \infty)$ for each $\alpha > 1$. In this section, we study the limit of the solutions u_α as $\alpha \to 1$. We start with two lemmas. The first one is another Bochner type formula.

Lemma 3.1. *Let $u(x,t)$ be a classical solution to the scaled $\alpha-$flow (2.2). If α is small, then there is a constant $C > 0$ such that*

$$\frac{\partial}{\partial t} e_\alpha(u) - \nabla_i \left((\delta_{ij} + 2(\alpha - 1)\frac{u_i^\beta u_j^\beta}{r^2 + |\nabla u|^2})\nabla_j e_\alpha(u) \right) \le C e_\alpha(u)(1 + |\nabla u|^2), \tag{3.1}$$

where $e_\alpha(u) := (r^2 + |\nabla u|^2)^\alpha$.

Proof. Again, we assume $\alpha - 1$ is small whenever necessary.

$$\begin{aligned}
& \nabla_i \left((\delta_{ij} + 2(\alpha - 1)\frac{u_i^\beta u_j^\beta}{r^2 + |\nabla u|^2})\nabla_j e_\alpha(u) \right) \\
= \; & \nabla_i \left(\alpha (r^2 + |\nabla u|^2)^{\alpha-1} (\delta_{ij} + 2(\alpha - 1)\frac{u_i^\beta u_j^\beta}{r^2 + |\nabla u|^2}) 2 u_k^\gamma u_{kj}^\gamma \right) \\
= \; & 2\alpha \nabla_i \left((r^2 + |\nabla u|^2)^{\alpha-1} u_k^\gamma u_{ki}^\gamma + 2(\alpha-1)(r^2 + |\nabla u|^2)^{\alpha-2} u_i^\beta u_j^\beta u_k^\gamma u_{kj}^\gamma \right) \\
= \; & 2\alpha \nabla_i \left((r^2 + |\nabla u|^2)^{\alpha-1} u_k^\gamma u_{ki}^\gamma + 2(\alpha-1)(r^2 + |\nabla u|^2)^{\alpha-2} u_i^\gamma u_k^\gamma u_j^\beta u_{kj}^\beta \right) \\
= \; & 2\alpha \nabla_i \left((r^2 + |\nabla u|^2)^{\alpha-1} u_k^\gamma u_{ki}^\gamma + u_i^\gamma u_k^\gamma \nabla_k (r^2 + |\nabla u|^2)^{\alpha-1} \right) \\
= \; & 2\alpha \nabla_i \left[u_k^\gamma \nabla_k (u_i^\gamma (r^2 + |\nabla u|^2)^{\alpha-1}) \right] \\
= \; & 2\alpha \left| u_{ki}^\gamma \right|^2 (r^2 + |\nabla u|^2)^{\alpha-1} + 4\alpha(\alpha-1)(r^2 + |\nabla u|^2)^{\alpha-2} u_{ki}^\gamma u_{jk}^\beta u_i^\gamma u_j^\beta \\
& + 2\alpha u_k^\gamma \nabla_i \nabla_k (u_i^\gamma (r^2 + |\nabla u|^2)^{\alpha-1}) \\
\ge \; & \alpha \left| u_{ki}^\gamma \right|^2 (r^2 + |\nabla u|^2)^{\alpha-1} + 2\alpha u_k^\gamma \nabla_k \nabla_i (u_i^\gamma (r^2 + |\nabla u|^2)^{\alpha-1}) - C(r^2 + |\nabla u|^2)^\alpha \\
\ge \; & \alpha \left| u_{ki}^\gamma \right|^2 (r^2 + |\nabla u|^2)^{\alpha-1} + 2\alpha (r^2 + |\nabla u|^2)^{\alpha-1} u_k^\gamma \nabla_k \frac{\partial u^\gamma}{\partial t} \\
& 2\alpha (r^2 + |\nabla u|^2)^{\alpha-1} u_k^\gamma \nabla_k (A^\gamma(u)(\nabla u, \nabla u)) - C(r^2 + |\nabla u|^2)^\alpha \\
\ge \; & \frac{1}{2} \left| u_{ki}^\gamma \right|^2 (r^2 + |\nabla u|^2)^{\alpha-1} + \frac{\partial}{\partial t} e_\alpha(u) - C e_\alpha(u)(1 + |\nabla u|^2).
\end{aligned}$$

□

The second lemma is a parabolic monotonicity formula. Such a formula for the harmonic map flow was first established by Struwe in [23] for the Euclidean case and by Chen and Struwe in [4] for general case. Let u be a solution to (1.1). Suppose R_M is the injectivity radius of M. For a fixed point p in M, choose the normal coordinates $\{x_i\}$ and a cut-off function φ supported in $B_{R_M}(p)$ such that $0 \le \varphi \le 1$ and $\varphi \equiv 1$ in a neighborhood of p. For $z = (p, t_0)$ with some $t_0 \in [0, \infty)$, set

$$G_z(x,t) = \frac{1}{|t - t_0|} e^{\frac{-|x|^2}{4|t-t_0|}}$$

and

$$\Psi_\rho^\alpha(u,z) = \rho^{2\alpha-2}\int_{T_\rho(t_0)} (1+|\nabla u|^2)^\alpha G_z \varphi^2 \sqrt{|g|}dxdt,$$

where $\sqrt{|g|}dx$ is the volume element of M and $T_\rho(t_0) = M\times[t_0-4\rho^2, t_0-\rho^2]$.

Lemma 3.2. *Let u be a smooth solution to (1.1) defined on $M\times[0,\infty)$ and $E_\alpha(u(t))\le E_0$. Then for z as above and for any $0<r<\rho\le R_M$,*

$$\Psi_r^\alpha(u,z)\le e^{c(\rho-r)}\Psi_\rho^\alpha(u,z)+cE_0(\rho-r),$$

with a uniform constant c depending only on M and N.

Proof. After a translation, we can assume $t_0=0$ and write $\Psi_\rho(u)$ for $\Psi_\rho^\alpha(u,z)$. Letting $u_\rho(y,s)=u(\rho y,\rho^2 s)$, we obtain

$$\Psi_\rho(u)=\int_{T_1}(\rho^2+g^{ij}(\rho y)\partial_{y_i}u_\rho\partial_{y_j}u_\rho)^\alpha G\varphi^2(\rho y)\sqrt{|g|}(\rho y)dyds.$$

In the following, for simplicity we write g^{ij} for $g^{ij}(\rho y)$ and the same convention applies to φ, $\bar\nabla g^{ij}$ and so on. Here we use $\bar\nabla$ to denote the gradient in local coordinates; i.e. $(\frac{\partial}{\partial x_1},\frac{\partial}{\partial x_2})$ and $\tilde\nabla$ to denote $(\frac{\partial}{\partial y_1},\frac{\partial}{\partial y_2})$. Denoting $\frac{\partial}{\partial y_i}u_\rho$ by $u_{\rho,i}$, we have

$$\begin{aligned}
&\frac{d}{d\rho}\Psi_\rho(u)\\
=\;& \int_{T_1}\alpha(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^{\alpha-1}(2\rho+y\cdot\bar\nabla g^{ij}u_{\rho,i}u_{\rho,j}+2g^{ij}u_{\rho,i}\frac{du_{\rho,j}}{d\rho})\cdot G\varphi^2\sqrt{|g|}dy\,ds\\
&+\int_{T_1}(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^\alpha G\frac{d}{d\rho}(\varphi^2\sqrt{|g|})dy\,ds\\
\ge\;& -\int_{T_1}2\alpha\frac{\partial}{\partial y_j}\left(\sqrt{|g|}(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^{\alpha-1}g^{ij}u_{\rho,i}G\right)\frac{du_\rho}{d\rho}\varphi^2dy\,ds\\
&-\int_{T_1}4\alpha(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^{\alpha-1}g^{ij}u_{\rho,i}\partial_{y_j}\varphi G\frac{du_\rho}{d\rho}\varphi\sqrt{|g|}dy\,ds\\
&+\int_{T_1}\alpha(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^{\alpha-1}y\cdot\bar\nabla g^{ij}u_{\rho,i}u_{\rho,j}G\varphi^2\sqrt{|g|}dy\,ds\\
&+\int_{T_1}(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^\alpha G2\varphi y\cdot\bar\nabla\varphi\sqrt{|g|}dy\,ds\\
&+\int_{T_1}(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^\alpha G\varphi^2\frac{y\cdot\bar\nabla\,|g|}{2\,|g|}\sqrt{|g|}dy\,ds\\
=\;& I+II+III+IV+V.
\end{aligned}$$

By definition of u_ρ,

$$\frac{du_\rho}{d\rho}=y\cdot\bar\nabla u+2\rho s\frac{\partial u}{\partial t}=\frac{2s}{\rho}(\frac{1}{2s}y\cdot\tilde\nabla u_\rho+\frac{\partial u_\rho}{\partial s}).$$

Since u_ρ satisfies,

$$\begin{aligned}
(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^{\alpha-1}\frac{\partial u_\rho}{\partial s} &= \frac{\partial}{\partial y_j}\left(\sqrt{|g|}(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^{\alpha-1}g^{ij}u_{\rho,i}\right)\\
&\quad+(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^{\alpha-1}A(u_\rho)(\tilde\nabla u_\rho,\tilde\nabla u_\rho),
\end{aligned}$$

we have

$$\begin{aligned}
I \quad & \geq -2\alpha\int_{T_1}(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^{\alpha-1}\Big(\frac{\partial u_\rho}{\partial s}-\frac{g^{ij}u_{\rho,i}y_j}{2|s|}\Big)\frac{du_\rho}{d\rho}G\varphi^2\sqrt{|g|}dy\,ds\\
\geq \quad & \int_{T_1}\frac{4\alpha|s|}{\rho}(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^{\alpha-1}\left|\frac{\partial u_\rho}{\partial s}-\frac{y\cdot\tilde{\nabla}u_\rho}{2\,|s|}\right|^2 G\varphi^2\sqrt{|g|}dy\,ds\\
- \quad & \int_{T_1}\frac{4\alpha\,|s|}{\rho}(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^{\alpha-1}\left|\frac{g^{ij}u_{\rho,i}y_j}{2\,|s|}-\frac{y\cdot\tilde{\nabla}u_\rho}{2\,|s|}\right|\left|\frac{\partial u_\rho}{\partial s}-\frac{y\cdot\tilde{\nabla}u_\rho}{2\,|s|}\right| G\varphi^2\sqrt{|g|}dy\,ds\\
\geq \quad & \int_{T_1}\frac{2\alpha|s|}{\rho}(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^{\alpha-1}\left|\frac{\partial u_\rho}{\partial s}-\frac{y\cdot\tilde{\nabla}u_\rho}{2\,|s|}\right|^2 G\varphi^2\sqrt{|g|}dy\,ds\\
& -C\int_{T_1}\frac{1}{\rho}(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^{\alpha-1}\left|\frac{g^{ij}u_{\rho,i}y_j}{2}-\frac{y\cdot\tilde{\nabla}u_\rho}{2}\right|^2 G\varphi^2\sqrt{|g|}dy\,ds.
\end{aligned}$$

Since $\{x_i\}$ are normal coordinates, we have $\left|g^{ij}(\rho y)-\delta^{ij}\right|\leq C\rho\,|y|$. The absolute value of the last term is not bigger than

$$\begin{aligned}
& C\int_{T_1}\rho^{-1}(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^{\alpha-1}\left|g^{ij}(\rho y)-\delta^{ij}\right|^2|y|^2|u_{\rho,i}|^2 G\varphi^2\sqrt{|g|}dy\,ds\\
\leq \quad & C\int_{T_1}\rho^{-1}(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^{\alpha-1}\rho^2|y|^4|u_{\rho,i}|^2 G\varphi^2\sqrt{|g|}dy\,ds\\
\leq \quad & C\int_{T_1}(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^{\alpha}(G+C)\varphi^2\sqrt{|g|}dy\,ds\\
\leq \quad & C\Psi_\rho(u)+C\max_{-4\leq s\leq -1}\int_M\rho^{2\alpha-2}(1+|\nabla u|^2)^\alpha\varphi^2\sqrt{|g|}dx\\
\leq \quad & C\Psi_\rho(u)+CE_0,
\end{aligned}$$

if $\rho<1$. Here we use the fact that for $s\in[-4,-1]$, $|y|^4G\leq G+C$. In summary, we have

$$\begin{aligned}
I \quad \geq \quad & \int_{T_1}\frac{2\alpha|s|}{\rho}(\rho^2+g^{ij}u_{\rho,i}u_{\rho,j})^{\alpha-1}\left|\frac{\partial u_\rho}{\partial s}-\frac{y\cdot\tilde{\nabla}u_\rho}{2\,|s|}\right|^2 G\varphi^2\sqrt{|g|}dy\,ds\\
& -C\Psi_\rho(u)-CE_0.
\end{aligned}$$

For the remaining terms, we have for a sufficiently small ϵ

$$\begin{aligned}
|II| &\leq \epsilon \int_{T_1} (\rho^2 + g^{ij} u_{\rho,i} u_{\rho,j})^{\alpha-1} \frac{4s^2}{\rho} \left| \frac{\partial u_\rho}{\partial s} - \frac{y \cdot \tilde{\nabla} u_\rho}{2|s|} \right|^2 G\varphi^2 \sqrt{|g|} dy\, ds \\
&\quad + C(\epsilon) \int_{T_1} \rho^{-1} (\rho^2 + g^{ij} u_{\rho,i} u_{\rho,j})^{\alpha-1} \left(g^{ij} u_{\rho,i} \partial_{y_j} \varphi \right)^2 \sqrt{|g|} dy\, ds \\
&\leq \epsilon \int_{T_1} (\rho^2 + g^{ij} u_{\rho,i} u_{\rho,j})^{\alpha-1} \frac{4s^2}{\rho} \left| \frac{\partial u_\rho}{\partial s} - \frac{y \cdot \tilde{\nabla} u_\rho}{2|s|} \right|^2 G\varphi^2 \sqrt{|g|} dy\, ds \\
&\quad + C(\epsilon) \int_{T_1} \rho \sum_k |\partial_{x_k} \varphi|^2 (\rho^2 + g^{ij} u_{\rho,i} u_{\rho,j})^{\alpha} \sqrt{|g|} dy\, ds \\
&\leq \frac{1}{2} I + C\Psi_\rho(u) + CE_0 + C \max_{-4 \leq s \leq -1} \int_M \rho^{1+2\alpha-2} (1 + |\nabla u|^2)^\alpha \sqrt{|g|} dx \\
&\leq \frac{1}{2} I + C\Psi_\rho(u) + CE_0.
\end{aligned}$$

Here we use again $\rho < 1$ and G is bounded on T_1. There is some constant C depending only on the geometry of M such that $\bar{\nabla} g^{ij}$ and $\bar{\nabla}|g|$ are bounded by C. Therefore we have

$$|III| + |V| \leq C\Psi_\rho(u) + CE_0$$

and

$$\begin{aligned}
|IV| &\leq \frac{1}{2} \Psi_\rho(u) + C \int_{T_1} (\rho^2 + g^{ij} u_{\rho,i} u_{\rho,j})^\alpha \left| y \cdot \bar{\nabla} \varphi \right|^2 G \sqrt{|g|} dy\, ds \\
&\leq \frac{1}{2} \Psi_\rho(u) + CE_0,
\end{aligned}$$

where we used the fact that $|y|^2 G$ is bounded on T_1. In conclusion, we show that for $\rho < 1$,

$$\frac{d}{d\rho} \Psi_\rho(u) \geq C\Psi_\rho(u) + CE_0.$$

The lemma follows from integrating this differential inequality. □

With these preparation, we now prove Theorem 1.2.

Proof. (i) Let z_i be a sequence of points in Σ which converges to $\tilde{z} = (\tilde{x}, \tilde{t})$. For any $0 < R < R_M$, by the definition of Σ, we have

$$\liminf_{\alpha \to 1} R^{2\alpha-2} \int_{T_R(z_i)} \varphi^2 e_\alpha(u_\alpha) G_{z_i} \sqrt{|g|} dx dt \geq \varepsilon_0.$$

Since $\int_M e_\alpha(u_\alpha) \sqrt{|g|} dx$ is uniformly bounded by E_0 and G_{z_i} converges to $G_{\tilde{z}}$ uniformly away from $\tilde{z}$, we can take $i \to \infty$ in the above inequality and switch the order of limits to get

$$\liminf_{\alpha \to 1} R^{2\alpha-2} \int_{T_R(\tilde{z})} \varphi^2 e_\alpha(u_\alpha) G_{\tilde{z}} \sqrt{|g|} dx dt \geq \varepsilon_0.$$

Since R is arbitrary, we know $\tilde{z} \in \Sigma$, which shows that Σ is closed.

For any $R > 0$, since $M \times [t^1, t^2]$ is compact, we can find a finite cover of Σ; i.e., $z_i = (x_i, t_i) \in M \times [t^1, t^2]$ such that

$$\Sigma \cap (M \times [t^1, t^2]) \subset \bigcup_{i=1}^{l} Q_{5R}(z_i)$$

and $\{Q_R(z_i)\}$ are disjoint. Here $Q_r(z)$ is defined to be $B_r(x) \times (t - r^2, t + r^2)$. Let $\bar{z}_i = (x_i, t_i + R^2)$. For some constant $\delta \in (0, 1/4)$ to be determined later, we have (by definition of Σ and for $\alpha - 1$ sufficiently small, in fact, for each i, $\alpha - 1$ is required to be smaller)

$$\begin{aligned} \frac{1}{2}\varepsilon_0 &\le (\delta R)^{2\alpha-2} \int_{t_i - 4\delta^2 R^2}^{t_i - \delta^2 R^2} \int_M \varphi^2 e_\alpha(u_\alpha) G_{z_i} \sqrt{|g|}\, dx dt \\ &\le C(\delta) R^{2\alpha-4} \int_{Q_R(z_i)} e_\alpha(u_\alpha) \sqrt{|g|}\, dx dt \\ &\quad + C\delta^{-2} e^{-\frac{1}{16\delta^2}} (\delta R)^{2\alpha-2} \int_{t_i - 4\delta^2 R^2}^{t_i - \delta^2 R^2} \int_M \varphi^2 e_\alpha(u_\alpha) G_{\bar{z}_i} \sqrt{|g|}\, dx dt \end{aligned} \tag{3.2}$$

for $1 \le i \le l$. Here in the last step above, we use the fact that

$$G_{z_i} \le \delta^{-2} e^{-\frac{1}{16\delta^2}} G_{\bar{z}_i} \text{ in } B_{R_M}(x_i) \times [t_i - 4\delta^2 R^2, t_i - \delta^2 R^2] \setminus Q_R(z_i).$$

By Lemma 3.2, the second term in the right hand side of (3.2) can be estimated as

$$\begin{aligned} C\delta^{-2} e^{-\frac{1}{16\delta^2}} \Psi^\alpha_{\delta R}(u_\alpha, \bar{z}_i) &\le C\delta^{-2} e^{-\frac{1}{16\delta^2}} (\Psi^\alpha_{\sqrt{t^1}/4}(u_\alpha, \bar{z}_i) + E_0) \\ &\le C(E_0, t^1) \delta^{-2} e^{-\frac{1}{16\delta^2}}. \end{aligned}$$

Hence, we can choose δ small to make it smaller than $\varepsilon_0/4$. Therefore,

$$R^2 \le R^{4-2\alpha} \le C \int_{Q_R} e_\alpha(u_\alpha) \sqrt{|g|}\, dx dt.$$

Since $Q_R(z_i)$ are disjoint, we have

$$\sum_{i=1}^{l} (5R)^2 \le C \sum_{i=1}^{l} \int_{Q_R(z_i)} e_\alpha(u_\alpha) \sqrt{|g|}\, dx dt \le C E_0.$$

By sending R to zero, we see that $\mathcal{P}^2(\Sigma \cap (M \times [t^1, t^2]))$ is finite. One can prove that Σ_t is a finite set in a similar way. If it is an infinite set, then we can find l distinct points $x_1, \cdots, x_l$ in Σ_t and $R > 0$ such that $B_R(x_i)$ are disjoint. For the same $\delta > 0$ as before, we may repeat the above argument for (x_i, t) to see

$$l(5R^2) \le C \sum_{i=1}^{l} \int_{Q_R((x_i,t))} e_\alpha(u_\alpha) \sqrt{|g|}\, dx dt \le C E_0 R^2.$$

This gives an upper bound on the number of points in Σ_t.

(ii) The proof in this part is similar to the proof of Theorem 1.1. When α is fixed, we know that there is no concentration for the Dirichlet energy, so we can use the small energy condition with (2.3) to obtain a C^0-bound of the gradient as in Lemma 2.4. However, as α goes to 1, the difference is that there may be a concentration point of the Dirichlet energy, but for $z \notin \Sigma$, we can find $1/2 > R > 0$ such that

$$\liminf_{\alpha \to 1} \Psi^\alpha_R(u_\alpha, z) < \varepsilon_0.$$

Claim: There is an $\varepsilon_0 > 0$ which we use in the definition of Σ and some $\delta > 0$ and some constant C depending on N, R, E_0 and ε_0 such that

$$\|\nabla u_{\alpha_k}\|_{C^0(P_{\delta R}(z))} \leq C.$$

Assume $z = (0,0)$ and set $r_1 = \delta R$ for some $\delta < 1/2$ to be determined. Suppose $r, \sigma \in (0, r_1)$, $r + \sigma < r_1$ and $z_0 = (x_0, t_0) \in P_r$. We need to show

$$\sigma^{2\alpha_k - 4} \int_{P_\sigma(z_0)} e_{\alpha_k}(u_{\alpha_k}) dvdt \leq C\varepsilon_0$$

if R and δ small. To see this, Lemma 3.2 implies

$$\begin{aligned} & \sigma^{2\alpha_k - 4} \int_{P_\sigma(z_0)} e_{\alpha_k}(u_{\alpha_k}) dvdt \\ \leq\ & c\sigma^{2\alpha_k - 2} \int_{P_\sigma(z_0)} e_{\alpha_k}(u_{\alpha_k}) G_{(x_0, t_0 + 2\sigma^2)} dvdt \\ \leq\ & c\sigma^{2\alpha_k - 2} \int_{T_\sigma(t_0 + 2\sigma^2)} \varphi^2 e_{\alpha_k}(u_{\alpha_k}) G_{(x_0, t_0 + 2\sigma^2)} dvdt \\ \leq\ & ce^{cR - \sigma} \Psi_R^{\alpha_k}(u_{\alpha_k}, (x_0, t_0 + 2\sigma^2)) + cE_0(R - \sigma). \end{aligned} \tag{3.3}$$

We can choose R to be small so that the last term is no larger than ε_0.

$$\begin{aligned} & \Psi_R^{\alpha_k}(u_{\alpha_k}, (x_0, t_0 + 2\sigma^2)) \\ \leq\ & cR^{2\alpha_k - 2} \int_{t_0 + 2\sigma^2 - 4R^2}^{t_0 + 2\sigma^2 - R^2} \int_M \varphi^2 e_{\alpha_k}(u_{\alpha_k}) G_{(x_0, t_0 + 2\sigma^2)} dvdt \\ \leq\ & cR^{2\alpha_k - 2} \int_{-4R^2}^{-R^2} \int_M \varphi^2 e_{\alpha_k}(u_{\alpha_k}) G_{(x_0, t_0 + 2\sigma^2)} dvdt + (\delta R)^2 E_0 R^{-2} \\ \leq\ & c\Psi_R^{\alpha_k}(u_{\alpha_k}, (x_0, t_0)) + \varepsilon E_0 + \delta E_0. \end{aligned} \tag{3.4}$$

Here in the last line we used the fact that on T_R, for any $\varepsilon > 0$, we can find δ so small such that

$$G_{(x_0, t_0 + 2\sigma^2)} \leq cG(x,t) + \varepsilon R^{-2},$$

which is (2.18) of [4]. Hence, by choosing ε, δ properly, we have

$$\sigma^{2\alpha_k - 4} \int_{P_\sigma(x_0, t_0)} e_{\alpha_k}(u_{\alpha_k}) dvdt \leq C\varepsilon_0 \tag{3.5}$$

for any $(x_0, t_0) \in P_r$ and $r + \sigma < r_1 = \delta R$.

We can find $\rho \in [0, r_1]$ such that

$$(r_1 - \rho)^{2\alpha_k} \sup_{P_\rho} e_{\alpha_k}(u_{\alpha_k}) = \max_{\sigma \in [0, r_1]} \left\{ (r_1 - \sigma)^{2\alpha_k} \sup_{P_\sigma} e_{\alpha_k}(u_{\alpha_k}) \right\}.$$

Let (x_1, t_1) be the point in P_ρ such that

$$e_0 \overset{\triangle}{=} e_{\alpha_k}(u_{\alpha_k})(x_1, t_1) = \sup_{P_\rho} e_{\alpha_k}(u_{\alpha_k}).$$

If $e_0(r_1 - \rho)^{2\alpha_k} \leq 4$, then

$$(\frac{r_1}{2})^{2\alpha_k} \sup_{P_{r_1/2}} e_{\alpha_k}(u_{\alpha_k}) \leq e_0(r_1 - \rho)^{2\alpha_k} \leq 4,$$

which means the claim is true. Hence, we may assume that $e_0(r_1-\rho)^{2\alpha_k} > 4$. Set $\lambda = e_0^{\frac{1}{2\alpha_k}}$ and

$$v(x,t) = u_{\alpha_k}(x_1 + \frac{x}{\lambda}, t_1 + \frac{t}{\lambda^2})$$

for $(x,t) \in B_1(0) \times [-1,0]$. Then v satisfies a scaled $\alpha-$flow equation

$$\begin{aligned}(\lambda^{-2} + |\nabla v|^2)^{\alpha_k - 1}\partial_t v &= \operatorname{div}\Big((\lambda^{-2} + |\nabla v|^2)^{\alpha_k-1}\nabla v\Big) \\ &\quad +(\lambda^{-2} + |\nabla v|^2)^{\alpha_k-1} A(v)(\nabla v, \nabla v).\end{aligned}$$

If we write $e(v)$ for $(\lambda^{-2} + |\nabla v|^2)^{\alpha_k}$, then we have $e(v)(0,0) = 1$ and

$$\begin{aligned}\sup_{B_1(0)\times[-1,0]} e(v) &\leq e_0^{-1} \sup_{P_{\frac{r_1+(2^{1/\alpha_k}-1)\rho}{2^{1/\alpha_k}}}} e_\alpha(u_\alpha) \\ &\leq e_0^{-1} \frac{e_0(r_1-\rho)^{2\alpha_k}}{(r_1 - \frac{r_1+(2^{1/\alpha_k}-1)\rho}{2^{1/\alpha_k}})^{2\alpha_k}} \\ &= \left(\frac{2^{1/\alpha_k}}{2^{1/\alpha_k}-1}\right)^{2\alpha_k} \leq 5\end{aligned}$$

if k is large. By Lemma 3.1 and (3.6),

$$\frac{\partial}{\partial t} e(v) - \nabla_i (a_{ij}(v)\nabla_j e(v)) \leq C e(v),$$

where (a_{ij}) is a symmetric matrix whose eigenvalues satisfy uniform elliptic condition. By a standard Moser iteration again, we have

$$\begin{aligned}1 &= e(v)(0,0) \leq C \int_{B_1(0)\times[-1,0]} e(v) \\ &\leq C\lambda^{4-2\alpha_k} \int_{t-\lambda^{-2}}^{t} \int_{B_{1/\lambda}(x)} (1 + |du_{\alpha_k}|)^{\alpha_k} dv dt \\ &\leq C\varepsilon_0.\end{aligned}$$

Here in the last step, we used (3.5). This is a contradiction if we choose ε_0 small. This concludes the proof of the claim.

We can establish higher order estimates for u_{α_k} in a smaller neighborhood as in the proof of Theorem 1.1 so that (ii) follows.

(iii) Applying the uniform bound of ∇u_α to (1.1), the same proof of Theorem 1.1 yields that u_α converges smoothly to u outside Σ. Then u satisfies the harmonic map flow equation on $M \times [0,\infty) \setminus \Sigma$. The rest of the proof is exactly the same as in Theorem 7.2.3 of [16]. □

Let $\mathcal{S}(u)$ be the singular set of the weak limit u; i.e. for any $(x,t) \notin \mathcal{S}(u)$, there is $r > 0$ such that $u|_{B_r(x)\times(t-r^2,t+r^2)}$ is smooth. It follows from Theorem 1.2 that

$$\mathcal{S}(u) \subset \Sigma.$$

In fact, thanks to the local energy inequality (2.1), we can say more about the position of $\mathcal{S}(u)$ in Σ. A point $z \in \Sigma$ is said to be a *rightmost* point of Σ if for some $r > 0$ we have

$$\Sigma \cap (B_r(x) \times (t-r^2, t)) = \emptyset.$$

Lemma 3.3. *Every rightmost point of* Σ *lies in* $\mathcal{S}(u)$.

Proof. Let $z = (x,t)$ be a rightmost point of Σ. Assume that $z \notin \mathcal{S}(u)$. By definition, there exist $r_1 > 0$ and $r_2 > 0$ such that

$$\Sigma \cap (B_{r_1}(x) \times (t - r_1^2, t)) = \emptyset \tag{3.6}$$

and

$$\|\nabla u\|_{C^0(B_{r_2}(x)\times(t-r_2,t+r_2))} \leq C. \tag{3.7}$$

We may assume that $r_1 > r_2$. There exists an $R \in (0, r_2)$ depending only on the C in (3.7) and ε_0 such that

$$|B_R(x)|(1+4C^2)^2 \leq \varepsilon_0/8. \tag{3.8}$$

Given this R, we then find $\rho > 0$ depending only on R, ε_0 and overall energy upperbound E_0 such that

$$\int_{M\setminus B_R(x)} (1+|\nabla u_\alpha|^2)^\alpha e^{-\frac{|x|^2}{4s}} \varphi^2 dv \leq \varepsilon_0/8 \tag{3.9}$$

for all $s \in (\rho^2, 4\rho^2)$. Since

$$(B_R(x) \times [t-4\rho^2, t-\rho^2]) \cap \Sigma = \emptyset,$$

by (i) of Theorem 1.2, we have for k sufficiently large

$$|\nabla u_{\alpha_k}|(y,s) \leq 2C \tag{3.10}$$

for $y \in B_R(x)$ and $s \in [t-4\rho^2, t-\rho^2]$. Now we can estimate for k large

$$\begin{aligned}
\Psi_\rho^{\alpha_k}(u,(x,t)) &= \rho^{2\alpha_k-2}\int_{T_\rho(t)} (1+|\nabla u_\alpha|^2)^\alpha G_z \varphi^2 dv dt \\
&\leq 3 \max_{s\in[t-4\rho^2,t-\rho^2]} \int_M (1+|\nabla u_{\alpha_k}|^2)^{\alpha_k} e^{-\frac{|x|^2}{4(t-s)}} \varphi^2 dv \\
&\leq \frac{7}{8}\varepsilon_0,
\end{aligned}$$

where we used (3.8), (3.9) and (3.10). This is a contradiction to the fact that $(x,t) \in \Sigma$. □

We now prove Theorem 1.3.

Proof. Since the initial value is smooth, by uniqueness, $u(x,t) = \hat{u}(x,t)$ for $t < T$. (i) follows immediately from Lemma 3.3.

For (ii), since u_α converges smoothly to u away from Σ_T, we have $\Sigma_T = \{p_i\}_{i=1}^k$. For $x \in M \setminus \Sigma_T$, by Theorem 1.2, we know u is smooth on $B_r(x) \times [T-r^2, T+r^2]$ for some small $r > 0$. This implies that $\nabla \hat{u}$ is bounded on $B_r(x) \times [T-r^2, T)$, which means that x is not one of the $\hat{p}_i$'s. On the other hand, if x is not a blow-up point for $\hat{u}$ at time T, then there exists $r > 0$ such that

$$|\nabla u|(x,t) \leq C \tag{3.11}$$

for (x,t) in $B_r(x) \times [T-r^2, T)$. The same proof as in Lemma 3.3 shows that $x \notin \Sigma_T$. Hence, $\{p_i\}$ and $\{\hat{p}_i\}$ are the same set of points. Assume $k = 1$. It remains to show $\hat{m} \leq m$. For $R > 0$ and $\delta > 0$, local energy inequality gives

$$\int_{B_R(p)} e_\alpha(u_\alpha)(T) dv \leq \int_{B_{2R}} e_\alpha(u_\alpha)(T-\delta) dv + CE_0 \frac{\delta}{R^2}. \tag{3.12}$$

For any $\varepsilon > 0$, choose R so that $\int_{B_{2R}(p)} e(\hat{u})(T) \le \varepsilon/6$ and $\mathrm{Vol}(B_{2R}(p)) \le \varepsilon/6$. Let $\delta > 0$ be a small number such that $CE_0 \frac{\delta}{R^2} \le \varepsilon/6$. Taking $\alpha \to 1$ in (3.12), we have

$$m \le \int_{B_{2R}(p)} e(\hat{u})(T-\delta) dv + \varepsilon/3.$$

Finally, letting δ go to zero, we obtain

$$m \le \int_{B_{2R}(p)} e(\hat{u})(T) dv + \hat{m} + \varepsilon/3 \le \hat{m} + \varepsilon/2.$$

The theorem follows by the arbitrariness of ε. $\square$

With Theorem 1.2 and Theorem 1.3, it is natural to ask whether u in Theorem 1.2 is the same as the Struwe solution after the first blow-up time. Given the nonuniqueness results [1] and [24], one can not exclude the possibility that u is different from the Struwe solution. On this issue, we would like to make the following remark,

Remark 3.4. *Consider maps from round S^2 to itself. According to* [2]*, there exists an initial value map u_0 of degree three such that Struwe's solution blows up at some finite time T and the homotopy class of the solution is changed for $t > T$. Hence the $\alpha-$flow solutions u_α with the same initial value can not converge strongly to Struwe's solution after T. A natural question is what we can say about Σ. See* [12].

4. AN APPLICATION

In this section, we apply our results about the $\alpha-$flow to the study of minimizing sequence of Dirichlet energy in a homotopy class. The following lemma is a variant of the main estimate in [18].

Lemma 4.1. *Let w be a map from B_1 to N satisfying the following scaled equation for some $R > 0$:*

$$\triangle w + (\alpha - 1) \frac{\nabla |\nabla w|^2 \cdot \nabla w}{R^2 + |\nabla w|^2} + A(\nabla w, \nabla w) = h, \tag{4.1}$$

where $h \in L^2$. There exists $\varepsilon_0 > 0$ such that if $E(w) < \varepsilon_0$ and $\alpha - 1$ is sufficiently small then

$$\|w - \bar{w}\|_{W^{2,2}(B_{1/2})} \le C(\|\nabla w\|_{L^2(B_1)} + \|h\|_{L^2(B_1)}).$$

Here $\bar{w}$ is the mean value of w on B_1.

Proof. The proof is similar to the main estimate in [18]. During the proof, we write $\|\cdot\|_{p,q}$ for $\|\cdot\|_{W^{p,q}(B_1)}$. Multiplying the equation by φ and taking the L^p norm, we have

$$\|\triangle(\varphi w)\|_{0,p} \le 2(\alpha-1) \|\varphi w\|_{2,p} + C \||\nabla(\varphi w)| |\nabla w|\|_{0,p} + C \|w\|_{1,p} + C \|h\|_{0,p}. \tag{4.2}$$

For $1 < p < 2$, the Hölder inequality implies that

$$\||\nabla(\varphi w)| |\nabla w|\|_{0,p} \le \|\nabla(\varphi w)\|_{0,q} \|\nabla w\|_{0,2},$$

where $q = 2p/(2-p)$. By the L^p-estimate, for $\alpha - 1$ small, we have

$$\|\varphi w\|_{2,p} \le C\varepsilon_0 \|\nabla(\varphi w)\|_{0,q} + C \|w\|_{1,p} + C \|h\|_{0,p}.$$

If we further assume that ε_0 is small, then it follows from the Sobolev embedding theorem

$$\|\varphi w\|_{2,p} \leq C\,\|w\|_{1,p} + C\,\|h\|_{0,p}\,.$$

Setting $p = 4/3$ and using Sobolev embedding again, we have

$$\|\varphi w\|_{1,4} \leq C(\|w\|_{1,4/3} + \|h\|_{0,4/3}).$$

With this, we can apply the interior L^2-estimate to (4.1) and multiply it by φ to get

$$\|w - \bar{w}\|_{W^{2,2}(B_{1/2})} \leq C(\|\nabla w\|_{L^2(B_1)} + \|h\|_{L^2(B_1)}).$$

□

We now prove Theorem 1.4.

Proof. Since u_i is smooth, we can find $\alpha_i > 1$ such that

$$E_{\alpha_i}(u_i) \leq E(u_i) + \mathrm{Vol}(M) + \frac{1}{i}. \tag{4.3}$$

We then consider the α_i-flow (1.1) with initial value u_i and denote the solution in Theorem 1.1 by $u_i(\cdot,t)$. Multiplying (1.1) by $(1 + |\nabla u_i|^2)^{\alpha_i - 1}\partial_t u_i$ and integrating by parts, we obtain a global energy inequality

$$E_{\alpha_i}(u_i) = E_{\alpha_i}(u_i(\cdot,1)) + \int_0^1 \int_M (1 + |\nabla u_i|^2)^{\alpha_i - 1} |\partial_t u_i|^2 \, dvdt.$$

By (4.3),

$$\lim_{i\to\infty} E_{\alpha_i}(u_i) = \lim_{i\to\infty} E(u_i) + \mathrm{Vol}(M).$$

Since u_i is a minimizing sequence of E,

$$\lim_{i\to\infty} E_{\alpha_i}(u_i(\cdot,1)) \geq \lim_{i\to\infty} E(u_i) + \mathrm{Vol}(M).$$

Therefore,

$$\lim_{i\to\infty} \int_0^1 \int_M (1 + |\nabla u_i|^2)^{\alpha_i - 1} |\partial_t u_i|^2 \, dvdt = 0. \tag{4.4}$$

Let u be the weak limit of u_i in $W^{1,2}(M \times [0,1])$ (by taking a subsequence if necessary), which is a weak solution to the harmonic map flow by Theorem 1.2. (4.4) implies that $u(\cdot,t)$ is (weak) harmonic map independent of t. Since $u_i(x,t)$ converges weakly to u in $W^{1,2}(M \times [0,1])$ and the trace operator $T : W^{1,2}(M \times [0,1]) \to L^2(M \times \{0\})$ is bounded linear operator, $u_i = u_i(\cdot,0)$ converges weakly to $u(\cdot,0)$ in L^2. Hence, $u = u(\cdot,0)$ is a harmonic map.

Instead of proving the energy identity for u_i directly, we will find another sequence of maps v_i, which is also minimizing in the same homotopy class and satisfies some perturbed harmonic map equation (see (4.7) below).

Thanks to (4.4), we may assume by taking subsequence if necessary

$$\int_{1/2}^1 \int_M |\partial_t u_i|^2 \, dvdt \leq \frac{1}{16^i}. \tag{4.5}$$

Consider

$$I_i = \left\{ t \in [1/2, 1] : \quad \int_M |\partial_t u_i(\cdot,t)|^2 \, dv \geq \frac{1}{2^i} \right\}.$$

It follows from (4.5) that

$$|I_i| \le \frac{1}{8^i},$$

where $|I_i|$ is the Lebesgue measure of I_i. Since

$$\sum_{i=1}^{\infty} |I_i| \le \sum_{i=1}^{\infty} \frac{1}{8^i} \le \frac{1}{4},$$

there exists at least one $t_0 \in [1/2, 1]$ such that for all i

$$\int_M |\partial_t u_i(\cdot, t_0)|^2 \, dv \le \frac{1}{2^i}. \tag{4.6}$$

For simplicity, denote $u_i(x, t_0)$ by v_i and write h_i for $\partial_t u_i(x, t_0)$. Hence, v_i satisfies the equation

$$\triangle v_i + 2(\alpha_i - 1)(\nabla^2 v_i, \nabla v_i)\nabla v_i (1 + |\nabla v_i|^2)^{-1} + A(\nabla v_i, \nabla v_i) = h_i. \tag{4.7}$$

As shown above, v_i converges weakly to u in in $W^{1,2}$. Moreover, by (4.3) and Lemma 2.1, v_i is also a minimizing sequence of E. With Lemma 4.1, it is well known that there exists finitely many points $x_1, \cdots, x_k$ such that v_i converges strongly to u in $W^{1,2}$ away from these points. By the removable singularity theorem, u can be extended to a smooth map on M. The proof of (1.2) will be given in Section 5.

Now, let us prove the second part of the theorem and assume that $\pi_2(N)$ is trivial. For simplicity, we assume $k = 1$. Let η be a smooth cutoff function which is 1 for $r \ge 1$ and 0 for $r \le 1/2$. For some $\rho > 0$, we define a new sequence of maps $\tilde{v}_i : M \to N$ such that $\tilde{v}_i$ is the same as v_i outside $B_\rho(x_1)$ and for $x \in B_\rho(x_1)$

$$\tilde{v}_i(x) = \exp_{u(x)} \left(\eta(\frac{|x|}{\rho}) \exp_{u(x)}^{-1} \circ v_i(x) \right),$$

where exp is the exponential map on N. We claim that

$$\|\tilde{v}_i - u\|_{W^{1,2}(M)} \to 0 \tag{4.8}$$

as $i \to \infty$. To see this, it suffices to consider $B_\rho(x_1) \setminus B_{\rho/2}(x_1)$ because $\tilde{v}_i \equiv u$ on $B_{\rho/2}(x_1)$ and $\tilde{v}_i \equiv v_i$ outside $B_\rho(x_1)$. On the other hand, Lemma 4.1 implies that v_i converges to u on $B_\rho(x_1) \setminus B_{\rho/2}(x_1)$ strongly in $W^{1,2}$ and C^β for some $\beta > 0$. Hence for large i, $v_i(B_{\rho(x_1)} \setminus B_{\rho/2}(x_1))$ lies in a small neighborhood of $u(x_1)$, where $\exp_{u(x)}^{-1}$ is a well defined smooth map (if ρ is small). Since $F(y) = \exp_{u(x)} \left(\eta(\frac{|x|}{\rho}) \exp_{u(x)}^{-1} y \right)$ is a smooth map from a neighborhood of $u(x_1)$ into itself, we have

$$\begin{aligned} \|\tilde{v}_i - u\|_{W^{1,2}(B_\rho \setminus B_{\rho/2}(x_1))} &= \|F \circ v_i - F \circ u\|_{W^{1,2}(B_\rho \setminus B_{\rho/2}(x_1))} \\ &\le C \|v_i - u\|_{W^{1,2}(B_\rho \setminus B_{\rho/2}(x_1))} \to 0 \quad \text{as } i \to \infty. \end{aligned}$$

Thus the claim follows. Since $\pi_2(N)$ is trivial, $\tilde{v}_i$ is in the same homotopy class as v_i. Noticing that v_i is a minimizing sequence of the Dirichlet energy and v_i converges weakly to u in $W^{1,2}$, we have

$$E(u) \le \lim_{i\to\infty} E(v_i) \le \lim_{i\to\infty} E(\tilde{v}_i), \tag{4.9}$$

which implies

$$E(u) = \lim_{i\to\infty} E(v_i).$$

Now, v_i converges to u strongly in $W^{1,2}$, which means that there is no energy concentration and Lemma 4.1 in turn shows that the convergence is in C^β for some $\beta > 0$. $\square$

5. An energy identity

Let u_i be a sequence of maps from M to N with bounded energy such that

(1) an $\varepsilon-$regularity lemma such as Lemma 4.1 holds for each u_i;

(2) u_i minimizes E within some fixed homotopy class.

In the previous section, we have constructed a sequence of v_i satisfying (1) and (2) by using $\alpha-$flow. The purpose of this section is to prove that for such a sequence u_i, there exists l harmonic maps $\omega_k(k = 1, \cdots, l)$ from $\mathbb{R}^2$ to N such that

$$\lim_{i\to\infty} E(u_i) = E(u) + \sum_{k=1}^{l} E(\omega_k),$$

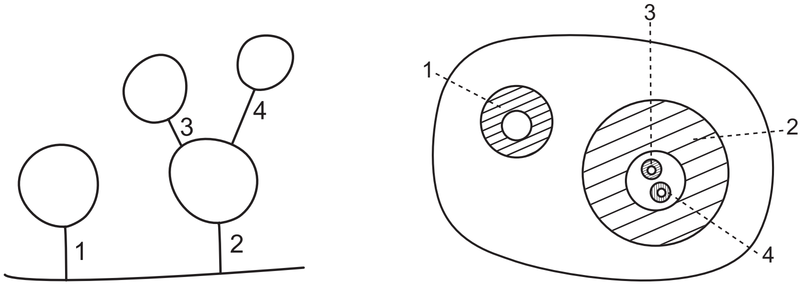
where u is the weak limit of u_i in $W^{1,2}$.

5.1. **Review of bubble tree construction.** Let us review the bubble tree construction due to Parker [17]. After taking a subsequence which is still denoted by u_i, we can decompose the domain into three parts. For each bubble points x_k, there is $c_{i,k} \in M$ and $\epsilon_{i,k}, \lambda_{i,k} > 0$ such that

(1) u_i converges to u on any compact subset of $M \setminus \{x_k\}$;

(2) if we rescale u_i on $B_{i\lambda_{i,k}}(c_{i,k})$ to a ball of radius i, then there is again a weak limit ω_k (a level 1 bubble) and finitely many bubble points so that the decomposition happens again at a higher level.

(3) $A_{i,k} \overset{\triangle}{=} B_{\epsilon_{i,k}}(c_{i,k}) \setminus B_{i\lambda_i,k}(c_{i,k})$ is the neck region. We denote x_k by p_k and $\omega_l(\infty)$ by q_k.



(a) bubble tree (b) domain decomposition

Figure 1. An example

There are finitely many bubbles including the so-called ghost bubbles which are constant maps and finitely many necks. For simplicity, we label bubbles and necks by only one index. So $A_{i,k}$ could be a neck region at any level. Suppose there are totally L such necks. An example of buble tree and the decomposition are illustrated in Figure 1. The shadow parts in Figure 1(b) stand for the neck regions.

We will need the following fact, which was proved during the construction of this bubble tree structure (see (1.6) in [17]): On a neck region,

$$\int_{A_{i,k}} e(u_i) = C_R < \varepsilon_1/6, \tag{5.1}$$

where ε_1 is the constant given in Lemma 5.4. To see this, recall that $\lambda_{i,k}$ is defined to be

$$\lambda_{i,k} = \text{largest } \lambda \text{ such that } \int_{B_{\epsilon_{i,k}(c_{i,k})} \setminus B_\lambda(c_{i,k})} e(u_i) \geq C_R$$

and $A_{i,k} \subset B_{\epsilon_{i,k}}(c_{i,k}) \setminus B_{\lambda_{i,k}}(c_{i,k})$. By choosing δ small, R large and a new subsequence if necessary, we may require

$$\int_{B_\delta \setminus B_{\lambda_{i,k} R}} e(u_i) < \varepsilon_1/3 \tag{5.2}$$

for i large.

To prove (1.2), it suffices to show

$$\sum_{k=1}^{L} \lim_{i\to\infty} \int_{A_{i,k}} e(u_i) = 0.$$

5.2. **An extension lemma.** Let p be a point in N and r be the injectivity radius of N. Consider a map $f : S^1 \to N$ whose image lies in $B_r(p)$. Define $\tilde{f} : B_2 \setminus B_1 \to N$ as

$$\tilde{f}(\theta, r) = \exp_p[(2-r)\exp_p^{-1} f(\theta)]. \tag{5.3}$$

It is obvious from the definition that $\tilde{f}(\theta, 1) = f(\theta)$ and $\tilde{f}(\theta, 2) = p$. We need to compute the energy of $\tilde{f}$. The chain rule implies

$$\left|\frac{\partial}{\partial r}\tilde{f}(\theta, r)\right| = \left|D(\exp_p)_{(2-r)\exp_p^{-1} f(\theta)} \cdot \exp_p^{-1} f(\theta)\right| \leq C d(f(\theta), p)$$

and

$$\left|\frac{\partial}{\partial \theta}\tilde{f}(\theta, r)\right| = \left|D(\exp_p)_{(2-r)\exp_p^{-1} f(\theta)} \cdot (2-r) D(\exp_p^{-1})_{f(\theta)} f'(\theta)\right| \leq C(2-r) f'(\theta).$$

Hence,

$$E(\tilde{f}) \leq C \int_{S^1}\int_1^2 \left(d(f(\theta), p)^2 + \frac{1}{r^2}(2-r)^2 \left|f'(\theta)\right|^2 \right) r dr d\theta.$$

We summarize the computation in a lemma.

Lemma 5.1. *For any $\varepsilon > 0$, there exists $\eta > 0$ depending only on ε and N such that if $f : S^1 \to N$ satisfies that*

$$\max_\theta [d(f(\theta), p) + |f'(\theta)|] < \eta,$$

then the Dirichlet energy of $\tilde{f}$ defined in (5.3) on $B_2 \setminus B_1$ is smaller than ε.

Remark 5.2. *We also need a similar result for*

$$\tilde{f}(\theta, r) = \exp_p[(r-1)\exp_p^{-1} f(\theta)].$$

The proof is the same as that of Lemma 5.1, so we omit it.

5.3. **A reference map.** We will construct a map from M to N whose image looks like the weak limit and bubbles connected by geodesics. It keeps the record of some topological information which will later be used to construct a new minimizing sequence.

Lemma 5.3. *There exists some positive constant σ depending only on N such that if f_1, f_2 are two continuous maps from Ω into N such that*

$$d(f_1(x), f_2(x)) \leq \sigma$$

for all $x \in \Omega$ and $f_1|_{\partial\Omega} = f_2|_{\partial\Omega}$, then there exists a homotopy deforming f_1 to f_2 with $\partial\Omega$ fixed.

We omit the proof since it is obvious.

Lemma 5.4. *There is a positive constant ε_1 depending only on N such that any $W^{1,2} \cap C^0$ map $g : S^2 \to N$ with $E(g) < \varepsilon_1$ is homotopic to a constant mapping.*

Proof. Consider the harmonic map flow $g(t)$ starting from g. Since the energy is not enough for a bubble (if ε_1 is small) then we know the flow is smooth for all time and converges sequencially and strongly to a harmonic map g_∞. In [18], it is proved that the energy of such a harmonic map is no less than some constant depending only N unless it is a constant map. By choosing ε_1 small, we may assume g_∞ is a constant map. If $t_n \to \infty$ is a sequence of time such that $g(t_n)$ converges smoothly to g_∞, we known from Lemma 5.3 that $g(t_n)$ is homotopic to g_∞ for n large. Hence g is homotopic to the constant map g_∞. □

The next lemma shows how to squeeze a little room on both ends of a long neck region without changing the energy much.

Lemma 5.5. *For i large so that $\delta >> \lambda_i R$, there is a diffeomorphism f from $B_\delta \setminus B_{\lambda_i R}$ to $B_{\delta/4} \setminus B_{4\lambda_i R}$ such that for any map $u : B_\delta \setminus B_{\lambda_i R} \to N$, we have*

$$1 - C(\frac{\delta}{\lambda_i R}) \leq \frac{E(u \circ f^{-1}, B_{\delta/4} \setminus B_{4\lambda_i R})}{E(u, E_\delta \setminus E_{\lambda_i R})} \leq 1 + C(\frac{\delta}{\lambda_i R}),$$

where $C(\frac{\delta}{\lambda_i R})$ is a constant which goes to zero if $\frac{\delta}{\lambda_i R}$ goes to infinity.

Proof. By conformal invariance of the Dirichlet energy, u can be regarded as a map from $S^1 \times [0, K]$ to N, where $K = \delta/(\lambda_i R)$. Define $\tilde{f} : S^1 \times [0, K] \to S^1 \times [4, K-4]$ by

$$\tilde{f}(\theta, \rho) = (\theta, 4 + \rho\frac{K-8}{K}).$$

It is straightforward to check

$$1 - C(K) \leq \frac{E(u \circ \tilde{f}^{-1}, S^1 \times [4, K-4])}{E(u, S^1 \times [0, K])} \leq 1 + C(K),$$

for some $C(K)$ such that $C(K)$ goes to zero if K goes to infinity. Set $s : S^1 \times [0, K] \to B_\delta \setminus B_{\lambda_i R}$ to be

$$s(\theta, \rho) = (\theta, \lambda_i R e^\rho).$$

Then $f : B_\delta \setminus B_{\lambda_i R} \to B_{\delta/4} \setminus B_{4\lambda_i R}$ defined by

$$f = s \circ \tilde{f} \circ s^{-1}$$

is the diffeomorphism we need. □

A remark about the notation is needed for the rest of the proof. For simplicity, we omit the subscript for necks as if there was only one neck. In fact, one should repeat the construction or proof for each neck region. By the nature of the following proof, this should cause no further difficulty. We write $B_\delta \setminus B_{\lambda_i R}$ for a neck region, omitting the center. We assume the neck connects the weak limit and a level 1 bubble. For a general neck, one should replace u with some bubble map ω_j.

We need δ, R and i to satisfy the following conditions.

(A1) Let $\varepsilon = \min\{\varepsilon_1, \xi/L\}/8$, where ξ is a positive number introduced in the next subsection and L is the total number of necks. Lemma 5.1 gives an η. Choose δ and R so that for each neck region $B_\delta \setminus B_{\lambda_i R}$, u restricted to ∂B_δ satisfies

$$\max_\theta |d(u,p)| + \left|\frac{d}{d\theta}u\right| \le \min\{\eta/2, \sigma/2\} \tag{5.4}$$

where p is the value of u at the bubble point and ω restricted to $\partial B_R \subset \mathbb{R}^2$ satisfies

$$\max_\theta |d(\omega,q)| + \left|\frac{d}{d\theta}\omega\right| \le \min\{\eta/2, \sigma/2\}, \tag{5.5}$$

where q is $\lim_{x\to\infty}\omega(x)$. Fix δ and R, choose some i so large that

(A2) (5.4) and (5.5) remains true if we replace u by u_i, ω by $u_i(\lambda_i \cdot)$, $\eta/2$ by η and $\sigma/2$ by σ;

(A3) $|u_i - u| \le \sigma/3$ for $x \in M \setminus B_\delta$ and $|u_i(\lambda_i x) - \omega(x)| \le \sigma/3$ for all $x \in B_R$ where σ is the constant in Lemma 5.3;

(A4) Let $C(\cdot)$ be the function given in Lemma 5.5. Let i be so large that $1 + C(\frac{\delta}{\lambda_i R}) < 2$.

Now we define a new map $w : M \to N$ so that

(1) $w = u_i$ on $M \setminus B_\delta$ and $B_{\lambda_i R}$;

(2) $w = u_i \circ f^{-1}$ on $B_{\delta/4} \setminus B_{4\lambda_i R}$, where f is the diffeomorphism constructed in Lemma 5.5;

(3) $w(\theta, r) = \exp_p[\frac{r-\delta/2}{\delta/2}\exp_p^{-1} u_i(\theta,\delta)]$ for $(\theta, r) \in B_\delta \setminus B_{\delta/2}$;

(4) $w(\theta, r) = w(\theta, \frac{\delta^2}{4r})$ for $(\theta, r) \in B_{\delta/2} \setminus B_{\delta/4}$;

(5) $w(\theta, r) = \exp_q[\frac{2\lambda_i R - r}{\lambda_i R}\exp_q^{-1} u_i(\theta, \lambda_i R)]$ for $(\theta, r) \in B_{2\lambda_i R} \setminus B_{\lambda_i R}$;

(6) $w(\theta, r) = w(\theta, \frac{(2\lambda_i R)^2}{r})$ for $(\theta, r) \in B_{4\lambda_i R} \setminus B_{2\lambda_i R}$.

It is easy to see that w is homotopic to u_i. Now let us consider the map w restricted to $B_{\delta/2} \setminus B_{2\lambda_i R}$. It follows from the construction that w maps $\partial B_{\delta/2}$ to p and $\partial B_{2\lambda_i R}$ to q. Hence, topologically it induces a map from S^2 to N if we identify $\partial B_{2\lambda_i R}$ with the north pole P_N and $\partial B_{\delta/2}$ with the south pole P_S. This is in fact a homotopically trivial map. To see this, consider a map $w_1 : \mathbb{R}^2 \to N$ which agrees with w on $B_{\delta/2} \setminus 2\lambda_i R$ and maps $B_{2\lambda_i R}$ to q and $\mathbb{R}^2 \setminus B_{\delta/2}$ to p. By the conformal invariance of E, we regard w_1 as a map from S^2 to N. By (A1), (A2) (A4) and (5.2) , the energy of this map is smaller than ε_1 in Lemma 5.4, hence it is homotopic to a constant map. Let $F : S^2 \times [0,1] \to N$ be the homotopy such that $F(\cdot, 0) = w_1(\cdot)$, $F(\cdot, 1) \equiv p$ and $F(P_S, t) = p$ for any $t \in [0,1]$. The curve $F(P_N, \cdot)$ connects q and p. Let $\gamma : [0,1] \to N$ be the shortest geodesic homotopic to this curve connecting q and p.

We can now define the reference map $\tilde{w}$. Let $\tilde{w} = w$ except that on $B_{\delta/2} \setminus B_{2\lambda_i R}$

$$\tilde{w}(\theta, r) = \gamma\left(\frac{\log r - \log(2\lambda_i R)}{\log(\delta/2) - \log(2\lambda_i R)}\right).$$

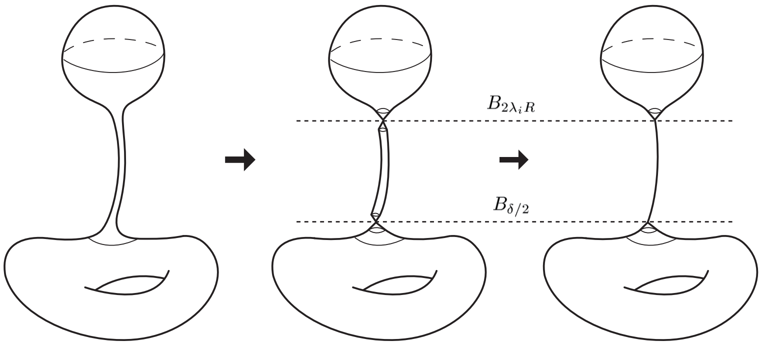


Figure 2. reference map

The above construction is illustrated by Figure 2. We claim that w and $\tilde{w}$ are homotopic. Since w and $\tilde{w}$ are the same except on $B_{2\delta} \setminus B_{2\lambda_i R}$, we construct the homotopy explicitly. For $(\theta, r) \in B_{\delta/2} \setminus B_{2\lambda_i R}$,

$$G((\theta,r),s) = \begin{cases} F(P_N, \frac{r-2\lambda_i R}{\delta/2-2\lambda_i R}), & 2\lambda_i R \leq r \leq r(s) \\ F((\theta, (\delta/2 - 2\lambda_i R)\frac{r-r(s)}{\delta/2-r(s)} + 2\lambda_i R), s), & r(s) \leq r \leq \delta/2, \end{cases}$$

where $r(s) = 2\lambda_i R + s(\delta/2 - 2\lambda_i R)$. From here, it is obvious that one can further deform $F(P_N, t)$ to γ.

If there are more than one neck region, we repeat the above construction for each neck.

5.4. **Proof of the energy identity.** Let us assume that the energy identity (1.2) is not true. Then there exists $\xi > 0$ and a subsequence (still denoted by u_i) such that

$$\lim_{i\to\infty} \sum_{k=1}^{L} \int_{A_{i,k}} e(u_i) \geq \xi.$$

Let $\tilde{w}$ be the reference map constructed above. We will show a contradiction by construct a new sequence $\tilde{u}_i$ in the same homotopy class such that

$$\lim_{i\to\infty} E(\tilde{u}_i) < \lim_{i\to\infty} E(u_i).$$

Define $\tilde{u}_i$ as follows

(1) $\tilde{u}_i = u_i$ outside the neck region $(B_\delta \setminus B_{\lambda_i R})$;

(2) $\tilde{u}_i(\theta, r) = \exp_p[\frac{r-\delta/2}{\delta/2} \exp_p^{-1} u_i(\theta, \delta)]$ for $(\theta, r) \in B_\delta \setminus B_{\delta/2}$;

(3) $\tilde{u}_i(\theta, r) = \exp_q[\frac{2\lambda_i R - r}{\lambda_i R} \exp_p^{-1} u_i(\theta, \lambda_i R)]$ for $(\theta, r) \in B_{2\lambda_i R} \setminus B_{\lambda_i R}$;

(4) $\tilde{u}_i(\theta, r) = \gamma(\frac{\log r - \log(2\lambda_i R)}{\log(\delta/2) - \log(2\lambda_i R)})$.

It remains to show first, the energy of $\tilde{u_i}$ in the neck region is smaller than $\xi/2$ for i large and second, $\tilde{u}_i$ is homotopic to $\tilde{w}$. For the first point, (A1) and Lemma 5.1 implies that the energy in $B_\delta \setminus B_{\delta/2}$ and $B_{2\lambda_i R} \setminus B_{\lambda_i R}$ for all necks is no more than $\xi/4$. Moreover, as i gets larger, then the energy on the geodesic part can be made as small as we want since the length of γ is fixed (See Section 5.3).

For the second point, if there is only one neck, then M is decomposed into three parts; $M \setminus B_{\delta/2}$, $B_{\delta/2} \setminus B_{2\lambda_i R}$ and $B_{2\lambda_i R}$. For the reference map $\tilde{w}$, the decomposition is fixed because we chose and fixed a large i in the construction.

For $\tilde{u}_i$, the center of B_δ and $B_{\lambda_i R}$ changes with i and so does the radius of $B_{2\lambda_i R}$. However, when restricted to the separating circles $\partial B_{\delta/2}$ and $\partial B_{2\lambda_i R}$, $\tilde{w}$ and $\tilde{u}_i$ are constant maps to the same points. This allows us to prove the homotopy between $\tilde{w}$ and $\tilde{u}_i$ on each of the three parts separately.

On $M \setminus B_{\delta/2}$, (A1) and (A3) show that $d(\tilde{w}, \tilde{u}_i) < \sigma$, which implies that there is a homotopy between them leaving $\partial B_{\delta/2}$ fixed. The bubble part $B_{2\lambda_i R}$ of $\tilde{w}$ and $\tilde{u}_i$ are homotopic for the same reason. On $B_{\delta/2} \setminus B_{2\lambda_i R}$ part, they are different parametrization of the same curve. This concludes our proof for (1.2) in the case of only one neck.

For the general case of multiple necks, the decomposition is more complicated but the same argument applies. To illustrate the idea, consider a bubble tree as shown in Figure 1(a). The necks are labelled from 1 to 4. The corresponding decomposition of M is illustrated in Figure 1(b). The shadow parts are neck regions. There are eight circles separating the neck regions and the bubble regions. Both $\tilde{w}$ and $\tilde{u}_i$ map these circles to p_i's and q_i's. The homotopy for bubble regions (including $M \setminus (B_{\delta/2}(x_1) \cup B_{\delta/2}(x_2))$ follows from Lemma 5.3 and the homotopy for neck regions is obvious because they are different parametrization of the same geodesics.

6. APPENDIX

In this appendix, we prove the local existence and uniqueness of the $\alpha-$flow equation

$$\partial_t u = \triangle_M u + (\alpha - 1)\frac{\nabla |\nabla u|^2 \cdot \nabla u}{1 + |\nabla u|^2} + A(u)(\nabla u, \nabla u) \tag{6.1}$$

for any smooth initial value $u_0 : M \to N \subset \mathbb{R}^k$.

As in the case of harmonic maps, there is an intrinsic way of writing the right hand side of (6.1). If we regard $(1 + |\nabla u|^2)^{\alpha-1}\nabla u$ as a section of the pull back bundle u^*TN and denote the induced connection of u^*TN by $\tilde{D}$, the righthand side can be written as

$$\tau_\alpha(u) := \frac{1}{(1 + |\nabla u|^2)^{\alpha-1}} \sum_i \tilde{D}_{e_i} \left((1 + |\nabla u|^2)^{\alpha-1} \nabla_{e_i} u \right),$$

where $\{e_i\}$ is an orthonormal basis of TM in some open set. In the following, we will call τ_α the $\alpha-$tension field of u. It is obvious that smooth solution to (6.1) is equivalent to that of the following

$$\frac{\partial u}{\partial t} = \tau_\alpha(u),$$

where we regard $u(\cdot, t)$ as maps into N. This allows us to consider a totally geodesic isometric embedding of N into $\mathbb{R}^k$ with some non-flat metric as in [9]. Precisely, there is a metric h on $\mathbb{R}^k$ and an embedding N into $\mathbb{R}^k$ such that the isometric embedding is totally geodesic and there exists an isometric involution i which acts on a tubular neighborhood $\mathcal{T}$ of N, leaving points of N fixed. By composing with this embedding, we regard u as a map from M into $(\mathbb{R}^k, h)$ and denote by τ_α^N and $\tau_\alpha^{\mathbb{R}^k}$ the $\alpha-$tension fields of u as a map into N and into $\mathbb{R}^k$ respectively. Since N is a totally geodesic submanifold, we have $\tau_\alpha^N(u) = \tau_\alpha^{\mathbb{R}^k}(u)$ (see page 108 in [9]).

Therefore, it suffices to study

$$\frac{\partial u^\beta}{\partial t} = \triangle_M u^\beta + (\alpha - 1)\frac{\nabla |\nabla u|^2 \cdot \nabla u^\beta}{1 + |\nabla u|^2} + \Gamma(u)\#\nabla u\#\nabla u, \tag{6.2}$$

where u^β is the components of u, $\triangle_M$ is the usual Laplacian on M and Γ is the Christoffel symbol of the Levi-Civita connection of $(\mathbb{R}^k, h)$. Since $|\nabla u|^2 = h_{\beta\gamma}(u)\nabla u^\beta \cdot \nabla u^\gamma$, when we expand $\nabla |\nabla u|^2$, there is an extra term involving the gradient of $h(u)$ which can be absorbed into the last term. The equation can be rewritten as

$$\frac{\partial u^\beta}{\partial t} = \triangle_M u^\beta + 2(\alpha - 1)\frac{\nabla^2_{ij} u^\gamma \nabla_i u^\gamma \nabla_j u^\beta}{1 + |\nabla u|^2} + \tilde{\Gamma}(u)\#\nabla u\#\nabla u. \tag{6.3}$$

Next, we start a routine iteration procedure to show the local existence of (6.3). Consider the following linear parabolic system

$$\frac{\partial u}{\partial t} = \triangle u + (\alpha - 1)\frac{(\nabla^2 u, \nabla v)\nabla v}{1 + |\nabla v|^2} + \tilde{\Gamma}(v)\#\nabla v\#\nabla v. \tag{6.4}$$

Let $w = u - u_0$, then w satisfies

$$\begin{aligned} \frac{\partial w}{\partial t} &= \triangle w + (\alpha - 1)\frac{(\nabla^2 w, \nabla v)\nabla v}{1 + |\nabla v|^2} + \tilde{\Gamma}(v)\#\nabla v\#\nabla v \\ &\quad + \triangle u_0 + (\alpha - 1)\frac{(\nabla^2 u_0, \nabla v)\nabla v}{1 + |\nabla v|^2}. \end{aligned} \tag{6.5}$$

For some $\mu \in (1, 2)$, set

$$V = \left\{ v \in C^{\mu,\mu/2}(M \times [0,T]) | \quad \|v\|_{C^{\mu,\mu/2}(M\times[0,T])} \le 1, v(0) \equiv 0 \right\}.$$

For each $v \in V$, the Schauder estimate of linear parabolic systems (see [8] and [19]) implies

$$\|w\|_{C^{\mu+1,\frac{\mu+1}{2}}(M\times[0,T])} \le C(\|w\|_{C^0(M\times[0,T])} + \|u_0\|_{C^{\mu+1}(M)} + 1). \tag{6.6}$$

Since $w(\cdot, 0) \equiv 0$, we have

$$\|w\|_{C^0(M\times[0,T])} \le TC(\|w\|_{C^0(M\times[0,T])} + \|u_0\|_{C^{\mu+1}(M)} + 1).$$

Choose T small so that

$$\|w\|_{C^0(M\times[0,T])} \le TC(\|u_0\|_{C^{\mu+1}(M)} + 1).$$

By the interpolation of the Hölder space, for $\sigma > 0$ such that $\mu = (1-\sigma)(\mu+1)$, we have

$$\|w\|_{C^{\mu,\mu/2}(M\times[0,T])} \le \|w\|^{\sigma}_{C^0(M\times[0,T])} \|w\|^{1-\sigma}_{C^{\mu+1,\frac{\mu+1}{2}}(M\times[0,T])}.$$

This implies that we can choose T sufficiently small so that $w \in V$.

Now start from any $v_0 \in V$. Let v_{k+1} be the solution of (6.4) with $v = v_k$ and zero initial value. We then have a uniform bound

$$\|v_k\|_{C^{\mu+1,\frac{\mu+1}{2}}(M\times[0,T])} \le C.$$

Using Schauder estimate again, we obtain uniform $C^{\mu+3,\frac{\mu+3}{2}}$ estimate for v_k. By taking a subsequence, we know v_k converges to some w in $C^{\mu+1,\frac{\mu+1}{2}}(M \times [0,T])$. Then $w + u_0$ is a solution to the $\alpha-$flow with initial value u_0.

If there are two smooth solutions u and w to the equation (6.3) defined on $[0,T]$, we can subtract the two equations, multiply both sides by $u-w$ and integrate over M to get

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_M |w-u|^2\,dv \quad \le \quad & -\int_M |\nabla(u-w)|^2\,dv \\ & +2(\alpha-1)\int_M (\nabla^2_{ij}(u^\beta-w^\beta))\frac{u_i^\beta u_j^\gamma}{1+|\nabla u|^2}(u^\gamma-w^\gamma)dv \\ & +C\int_M |u-w|^2\,dv + C\int_M |\nabla u-\nabla w|\,|u-w|\,dv.\end{aligned}$$

For the second term in the right hand side, integrating by parts and noticing that $\frac{u_i^\beta u_j^\gamma}{1+|\nabla u|^2}\nabla_i(u^\beta-w^\beta)\nabla_j(u^\gamma-w^\gamma)\ge 0$ yields

$$\frac{d}{dt}\int_M |u-w|^2\,dv \le C\int_M |u-w|^2\,dv,$$

which implies $u\equiv w$ on $M\times[0,T]$ if $u=w$ for $t=0$. It follows immediately from the uniqueness and the involution isometry $i:\mathcal{T}\to\mathcal{T}$ that if u_0 is a map from M to N, the image of the local solution $u(x,t)$ obtained above lies in N.
